Does risk equalization reduce the viability of voluntary deductibles?

ABSTRACT: Theoretically, a risk averse consumer takes a deductible if the premium rebate (far) exceeds his/her expected out-of-pocket expenditures. In the absence of risk equalization, insurers are able to offer high rebates because those who select into a deductible plan have below-average expenses. This paper shows that, for high deductibles, such rebates cannot be offered if risk equalization would “perfectly” adjust for the effect of self selection. Since the main goal of user charges is to reduce moral hazard, some effect of self selection on the premium rebate can be justified to increase the viability of voluntary deductibles.

Keywords: health insurance; voluntary deductibles; moral hazard; risk aversion; self selection; risk equalization

JEL Classification: I11, D82, D84, G22

1. Introduction

In a number of health insurance schemes the insured can opt for a voluntary deductible in return for a premium rebate. The main goal of these deductibles is to reduce moral hazard. The extent to which this goal will be achieved is greatly affected by the number of insured choosing a deductible. Obviously, this number is positively correlated with the rebate *offered* by insurers and negatively correlated with the rebate *demand*ed by the insured.

In free, unregulated health insurance markets insurers can offer high rebates due to the effect of self selection. Self selection occurs because, within a premium-risk group, low-risk individuals have a greater incentive to opt for a deductible than high-risk individuals. However, in an increasing number of countries there is a system of risk equalization in which insurers receive a payment for the relatively high risks in their insurance pool and contribute a payment for the relatively low risks. To some extent, these equalization payments will adjust for differences in health status between the insured who choose a deductible and those who do not. The goal of this paper is to indicate whether the rebates offered in the *absence* of (perfect) risk equalization, can still be offered in the *presence* of “perfect” risk equalization. If the answer is negative then the viability of voluntary deductibles will be reduced, i.e. numbers of insured opting for a deductible will be lower. Consequently, moral hazard reductions will be smaller. In this context, “perfect” risk equalization refers to an equalization system fully adjusting for the effect of self selection. The rationale of this paper is that countries like Switzerland and the Netherlands tend to improve risk equalization and consider voluntary deductibles as an appropriate instrument to reduce moral hazard.

We analyzed panel data from Switzerland with information on expenditures and actual choice of deductible of 134,758 Swiss insured. Theoretically, risk averse insured take a deductible *only if* the premium rebate (far) exceeds their expected out-of-pocket expenditures, i.e. if they expect to obtain a financial gain. In the first step of the analysis we estimated the actual financial gain (i.e. premium rebate minus out-of-pocket expenditures) obtained by the group of insured with voluntary deductible

1
2
3 d in 2003. In the second step we examined whether the rebate actually offered for d could have
4
5 been offered in the presence of “perfect” risk equalization.
6

7
8 Prior to the empirical results, we theoretically consider (the composition of) both the *demanded*
9
10 and *offered* premium rebate. Section 2 is concerned with the *demanded* premium rebate and uses the
11
12 expected-utility model to show why risk averse consumers take a deductible *only if* they expect to
13
14 obtain a financial gain. Section 3 is concerned with the *offered* premium rebate and considers in more
15
16 detail how this rebate will be reduced by improvements in the risk equalization system. Section 4
17
18 describes the data used, followed by a discussion of the methods in Section 5 and a report of the
19
20 results in Section 6. Section 7 concludes this study and discusses some policy implications.
21
22
23
24
25

26 **2. Demanded premium rebate**

27
28 If an expected-income optimizing consumer with mandatory health insurance would be risk
29
30 neutral and would face no transaction costs then he/she would take a deductible if the premium rebate
31
32 exceeded the product of the possible losses z_1, z_2, \dots, z_h and the probabilities p_1, p_2, \dots, p_h of these
33
34 losses to occur. The possible loss z_h equals the costs of health intervention h that have to be paid
35
36 out-of-pocket. The maximum value of $\sum_1^n z_h p_h$ equals the deductible amount d , since the
37
38 expenditures above this amount are reimbursed by the insurer.
39
40
41
42
43

44
45 In both economics and psychology it is widely argued that individuals consider more than (just)
46
47 the expected value $\sum z_h p_h$ in making choices under uncertainty. Arguing that a gain of 200 is not
48
49 necessarily ‘worth’ twice as much as a gain of 100, Daniel Bernoulli and Gabriel Cramer
50
51 hypothesized that an individual evaluates choices under uncertainty by the expected utility
52
53 $U = U(z_h p_h)$ instead of the expected value (von Neumann and Morgenstern, 1944). In existing
54
55 literature the *von Neumann-Morgenstern expected utility model* is widely used to model the demand
56
57 for insurance. Since the demand for deductibles is in fact the opposite of the demand for insurance,
58
59
60
61
62
63
64
65

1
2
3 the model can also be used to consider the choice whether to take a deductible, starting from full
4 coverage. In the following two sections we assume the consumer to be risk averse. Notice that the
5 context of this study is *mandatory* health insurance, in which individuals are *obliged* to insure.
6
7

8
9
10 Theoretically, these insured are not necessarily risk averters; they could be risk lovers. Nonetheless, it
11 is doubtful whether consumers are risk loving in the context of *health* insurance.
12
13

14
15 Similar to existing literature on the demand for health *insurance*, the expected-utility model used
16 here does not take into account moral hazard. We further assume that individuals face no transaction
17 costs in case of switching from a non-deductible to a deductible plan or the other way around. The
18 role of transaction costs will be discussed in Section 2.3.
19
20
21
22
23

24 25 **2.1 Expected-utility theory and the demand for insurance**

26
27 According to the expected-utility model, the utility function of a risk averse consumer is
28 characterized by a diminishing marginal utility of income, as shown in figure 1. If the consumer is
29 assumed to have income I_0 corresponding to utility $U(I_0)$, and if the probability to incur medical
30 expenditures z equals p and the probability to have no medical expenditures equals $1 - p$, then
31 his/her expected income equals $E(I)$, ceteris paribus.
32
33
34
35
36
37
38
39
40
41

$$42 \quad E(I) = p * (I_0 - z) + (1 - p) * I_0 = I_0 - p * z \quad (1)$$

43
44
45
46
47 Accordingly, the consumer's expected utility in a situation without insurance equals $E(U(I))$, as
48 shown in figure 1.
49
50
51
52

$$53 \quad E(U(I)) = p * U(I_0 - z) + (1 - p) * U(I_0) = U(I_0) - p * (U(I_0) - U(I_0 - z)) \quad (2)$$

54
55
56
57
58 [Figure 1]
59
60
61
62
63
64
65

1
2
3 At a certain moment the consumer is offered an insurance policy for an actuarially fair premium
4 $I_0 - E(I)$. This insurance policy takes away the uncertainty about whether and when there will be
5
6 an income loss because of medical expenditures z . Consequently, the actual utility of income after
7
8 paying the actuarially fair premium $I_0 - E(I)$ is higher than the expected utility $E(U(I))$ in a
9
10 situation *without* insurance. The utility gain of this insurance policy equals D-C, as shown in figure 2.
11
12
13
14
15
16
17

18 [Figure2]
19
20
21
22

23 So, a rationally behaving risk averse consumer will always purchase insurance for an actuarially
24 fair premium. Moreover, he/she will also buy insurance for a higher premium, as long as the loading
25 fee does not exceed C-E. The maximum acceptable loading fee can be defined as the maximum
26
27 amount that the insured is willing to pay for insurance, apart from the actuarially fair premium.
28
29
30
31
32

33 2.2 Expected-utility theory and the demand for voluntary deductibles 34

35 In case of voluntary deductibles in mandatory health insurance we must go the other way around
36 to approach the minimum compensation C_{min} demanded by an insured to be induced to take a
37
38 deductible. Let us assume that $U(I)$ in figure 3 is the utility curve of a risk averse consumer with a
39
40 mandatory policy with full coverage and income I_0 (after the insurance premium). Notice that this
41
42 starting point differs from that in the previous section.
43
44
45
46
47

48 At a certain moment, the consumer is offered the possibility to take a deductible d in return for
49 an actuarially fair premium rebate PR that equals his/her expected out-of-pocket expenditures. We
50
51 assume p to be the probability of medical expenditures to exceed d and assume $1 - p$ to be the
52
53 probability of medical expenditures to be zero. For reasons of simplicity, the probability to incur
54
55 medical expenditures in between is assumed to be zero. Accordingly, the actuarially fair premium
56
57 rebate PR equals $p * d$. Consequently, having a deductible results in income $I_0 + PR - d$ if
58
59
60
61
62
63
64
65

1
2
3 medical expenditures exceed the deductible amount and results in income $I_0 + PR$ if medical
4
5 expenditures are zero, as shown in figure 3. The expected income $E_d(I)$ in case of a deductible with
6
7 an actuarially fair premium rebate equals:
8
9

$$10 \quad E_d(I) = p * (I_0 + PR - d) + (1 - p) * (I_0 + PR) = I_0 \quad (3)$$

11

61
62
63
64
65

Expected utility $E_d(U(I))$ is lower than $U(I_0)$ since the consumer is a risk averter and a deductible plan results in more uncertainty about the level of income than full insurance.

$$E_d(U(I)) = p * U(I_0 + PR - d) + (1 - p) * U(I_0 + PR) \quad (4)$$

[Figure 3]

To induce insured the consumer to take a deductible, the insurer has to increase the premium rebate with compensation C such that $E_d(U(I))$ equals or exceeds $U(I_0)$, as shown in figure 4. We define the *minimum compensation* C_{min} , such that $E_d(U(I))$ equals $U(I_0)$. So, the minimum compensation is in fact the opposite of the maximum loading fee discussed in Section 2.1. Whereas a risk avers consumer is willing to pay a loading fee for an insurance policy, he/she demands a compensation to be induced to take a deductible. As shown in figure 4, C increases both $I_0 + PR - d$ and $I_0 + PR$, resulting in a higher expected income and a higher expected utility in case of a deductible.

[Figure 4]

1
2
3 In a study on the (hypothetical, survey-) choice whether to take a deductible among the Dutch
4 privately insured, Van de Ven and Van Praag (1981) found that, for all deductible amounts included,
5 the premium rebate was about 80 percent higher than the actuarially fair rebate. This implies that
6 these insured would demand for a rebate nearly twice the expected out-of-pocket expenditures before
7 they would be willing to take a deductible.
8
9

16 **2.3 Expected compensation**

17 Among others, Edwards (1955), Kahneman and Tversky (1979), Machina (1982), Fishburn
18 (1983) argue that choices under uncertainty are not only influenced by risk aversion, but also by
19 individual preferences and perceptions about both probabilities and prices. Burrows et al. (1993)
20 report of inertia as being an important explanation for the fact that people are not switching in
21 situations where this would benefit them in terms of (expected) utility. Kunreuter and Pauly (2004)
22 argue that decisions are not always ‘optimal’ in terms of expected utility as a result of search and
23 transaction costs, which occur as a consequence of searching for the best policy and switching from
24 the current policy to a new one. Insured probably have greater inclination to switch between two
25 policies in a situation where these costs are low than in a situation where these costs are high, *ceteris*
26 *paribus*.
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41

42 Following both this literature and the basic assumptions underlying the expected utility model, the
43 *demanded compensation* is probably affected by a mixture of factors, such as the expected out-of-
44 pocket expenditures, the deductible amount d , the level of risk aversion r (Pratt, 1964), the level of
45 income I , the extent of transaction and search costs, and personal characteristics such as inertia. We
46 do not explore these individual components in further detail, since the remainder of this paper is
47 focused on the *total* demanded compensation regardless of its composition.

2.4 Conclusion

According to the previous consideration we assume insured i to take a voluntary deductible d if the offered premium rebate OPR exceeds his/her demanded premium rebate DPR .

$$DPR_{i,d} < OPR_d \quad (5)$$

with $DPR_{i,d}$ as the sum of the expected out-of-pocket expenditures $E(OOPE)_{i,d}$ and the minimum compensation $C_{\min,i,d}$.

$$DPR_{i,d} = E(OOPE)_{i,d} + C_{\min,i,d} \quad (6)$$

3. Offered premium rebate

In a free, unregulated health insurance market the offered premium rebate OPR for a certain deductible can be based on out-of-pocket expenditures, reductions in moral hazard, reductions in administration costs, and the effect of self selection, due to that deductible (Bakker et al., 2000).

3.1 Out-of-pocket expenditures and cost reductions

The insured with a deductible pay the expenditures up to the deductible amount out of their own pocket, resulting in a shift of costs from the insurer to the insured. In a competitive health insurance market, insurers will be forced to reflect these out-of-pocket expenditures in the premium rebate.

A second component is the reduction in moral hazard. Moral hazard can be defined as the increase in (more expensive) medical consumption because of insurance. Based on the RAND-experiment, Keeler et al. (1988) conclude that full insurance coverage leads to about 70 percent higher medical expenditures than no insurance coverage. So, compared to full coverage, deductibles are expected to reduce total expenditures. In the RAND experiment a 95-percent coinsurance plan with a stop-loss of

1
2
3 \$ 1,000 resulted in 31 percent lower medical expenditures than a full-coverage plan (Manning, 1987).
4
5 The average medical expenditures of those not having a deductible in the RAND-experiment were \$
6
7 749 (in 1984 US-dollars). A more recent study by Van Vliet (2004) shows that in the Dutch private
8
9 health insurance market of 1996 a deductible of Dfl. 1,750 led to a reduction in medical expenditures
10
11 of about 14 percent. The average expected medical expenditures of the insured having that deductible
12
13 were Dfl. 2,548 (in 1996 Dutch guilders).
14
15

16
17 In a reimbursement scheme, a third component could be a reduction in administration costs. Part
18
19 of the insured will not send their bills to the insurer before the total amount exceeds the deductible.
20
21 Consequently, the insurer does not have to handle the bills of those whose expenditures remain below
22
23 the deductible amount in the accounting period. However, many health insurance schemes are
24
25 characterized by arrangements between insurers and providers of care. Due to these arrangements a
26
27 reduction in administration costs is expected to be negligible since (a part of) the bills are sent
28
29 directly from the provider to the insurer, with the insured being notified afterwards. Hence, we
30
31 assume a reduction in administration costs to be absent.
32
33
34
35
36

37 **3.2 Self selection**

38
39 In a competitive health insurance market without risk equalization, the premium rebate is not just
40
41 a reflection of out-of-pocket expenditures and the cost reductions mentioned above, but also
42
43 comprises the effect of self selection. Self selection occurs because high risks have a greater incentive
44
45 to buy (more) insurance coverage than low risks within the same premium-risk group. Many studies
46
47 found evidence of self selection in health insurance (e.g. Browne 1992, Gardiol et al. 2005, Beck
48
49 2004). In the context of the present study, self selection occurs because the healthy insured have a
50
51 greater incentive to opt for a voluntary deductible than the unhealthy insured (given a certain
52
53 premium rebate). In a heterogeneous risk pool self selection results in market segmentation such that
54
55 those who choose the deductible on average are healthier and have lower expenditures than those who
56
57 do not choose a deductible, ceteris paribus. Competition will force the insurer to increase the
58
59
60
61
62
63
64
65

1
2
3 premium for full coverage and decrease the premium (i.e. increase the premium rebate) for the
4 deductible plan. Consequently, the premium rebate for a certain deductible is not only based on out-
5 of-pocket expenditures plus the reduction in moral hazard due to that deductible, but also on
6 differences in ex-ante health status between those whose choose a deductible and those who do not.
7
8 The more heterogeneous premium-risk groups are the larger will be this effect of self selection.
9
10
11
12
13
14

15 In the presence of risk equalization among insurers, the effect of self selection on the premium
16 rebate will be smaller. If the equalization payments do “perfectly” adjust for expenditure differences
17 due to differences in ex-ante health status between the healthy and the unhealthy then the *effect* of self
18 selection on the premium rebate is zero (although there might be substantial self selection). For
19 instance, this scenario occurs if the level of deductible is included as a risk factor in the risk
20 equalization system.
21
22
23
24
25
26
27
28
29

30 **3.3 Conclusion**

31
32 If the equalization payments fully adjust for the effect of self selection then the offered premium
33 rebate can be based exclusively on the expected out-of-pocket expenditures $E(OOPE_d)$, and
34 expenditure reductions MR_d due to decreased moral hazard.
35
36
37
38
39
40
41
42

$$43 \quad OPR_d = E(OOPE_d) + MR_d \quad (7)$$

44
45
46
47

48 **4. Data**

49
50 To estimate the actual financial gains obtained in the Swiss basic health insurance and to examine
51 whether the premium rebates actually offered could have been offered in the presence of perfect risk
52 equalization, we analyzed 2003-data from a Swiss sickness fund.

64
65

4.1 Swiss sickness fund insurance

Since the Revised Health Insurance Law came into force in January 1996, all Swiss residents must have basic health insurance.

4.1.1 General

In 2002, there were 93 insurance companies operating under the health insurance law, which defines the scope of the benefits package as well as the conditions under which insurers and providers of care are operating. Among others, the package includes inpatient and outpatient care, physician's services, physiotherapy, laboratory analyses, health care at home, nursing home care, technical aid, medicaments from pharmacy and physicians, and alternative and complementary benefits. Insurers are obliged to accept all applicants, thereby avoiding explicit preferred-risk selection in principle. The insured may change insurer twice per year. To equal out different starting positions of the competing insurers when open enrollment started in 1996 and to avoid preferred-risk selection, government created a solidarity fund responsible for risk equalization (Beck et al., 2003). Every canton has its own risk equalization system, which takes into account age and gender and equalizes the actual net expenditures, i.e. the expenditures reimbursed by the insurer.

4.1.2 Individual deductibles

There are user charges in the form of individual deductibles starting from a mandatory minimum. The insured can reduce their premium by opting for a higher deductible. In order to protect solidarity, premium rebate limits are set by the federal government. In addition to these deductibles there is a coinsurance of 10 percent up to a maximum of CHF 600 per person per year for all medical expenditures above the deductible. During inpatient care those from single-occupant households must pay hotel-type expenses of CHF 10 per day. During the years in our data the mandatory deductible was CHF 230 and the voluntary deductibles on top of the mandatory deductible were CHF 170, 370, 970 and 1,270 per person per year. A voluntary deductible of CHF 170 (€ 110, 2006) resulted in a

1
2
3 premium rebate of up to 8 percent. For voluntary deductibles of CHF 370, 970 and 1,270 (€ 235, €
4 610 and € 800 respectively, 2006) the rebates were at most 15, 30 and 40 percent of the community-
5 rated premium per insurer per canton, respectively. Children are exempted from mandatory
6 deductibles and their voluntary deductible options are all lower than the options for adults and seldom
7 chosen.
8
9

10 11 12 13 14 15 16 **4.2 Data**

17
18 The data are taken from administrative sources and contain background information and medical
19 expenditures for insured from 4 Swiss cantons who were enrolled in the sickness fund in 1998. These
20 insured, all older than 26 years, were followed during the period 1998-2003, starting with n=197,120
21 and ending up with n=134,758. The main reasons for drop-out were leaving to another region or
22 leaving the country, switching to another insurance company and deaths. The data set includes
23 information on age, gender, medical expenditures, insurance premium, deductible level, premium
24 rebate, region and years of enrollment. Medical expenditures are divided into eleven categories of
25 medical care, i.e. physician care, medicaments from physicians, medicaments from pharmacies,
26 physiotherapy, laboratory analyses, stationary and ambulatory hospital care, health care at home,
27 nursing home care, technical aid, and other. Apart from nursing home care, this benefit package is
28 comparable to that in other health insurance schemes. To generalize the results and conclusions,
29 expenditures for nursing home care were not taken into account in the empirical analysis.
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45

46 The first line of table 1 shows the gross expenditures, i.e. the expenditures registered by the
47 insurer, per deductible amount. These expenditures are probably incomplete because of unfiled
48 claims. The reason is that some of the insured will send their bills to their insurer *only if* the total
49 amount exceeds the deductible, i.e. if they expect to get any reimbursement. Obviously, the amount of
50 unfiled claims is expected to increase with a higher deductible.
51
52
53
54
55
56
57

58 To get a better indication of the expenditure differences among insured with different deductible
59 amounts, table 1 also shows the average expenditures above CHF 1,500 and the proportion of insured
60
61
62
63
64
65

1
2
3 with expenditures exceeding CHF 1,500. These expenditures are not affected by unfiled claims, since
4 all insured with expenditures exceeding CHF 1,500, in principle, send all bills to the insurer in order
5 to get (some) reimbursement. For these insured the gross expenditures registered by the insurance
6 company reflect to their actual expenditures.
7
8
9
10
11
12
13
14

15 [Table 1]
16
17
18
19

20 At first glance, table 1 reveals that there is a high correlation between the level of deductible and
21 expenditures > CHF 1,500. This can be the result of both a reduction in moral hazard and the effect of
22 self selection. Self selection is evident in the correlation between the level of deductible and age.
23
24
25
26
27

28 5. Method 29

30 In the first part of the empirical analysis we quantified the actual financial gain obtained for
31 voluntary deductible d in 2003. In the second part we examined whether the premium rebate offered
32 for deductible d could have been offered in the presence of “perfect” risk equalization.
33
34
35
36
37
38

39 5.1 The actual financial gain 40

41 For insured i we calculated the actual financial gain $C_{i,d}$ from having a voluntary deductible d
42 as the offered premium rebate for this deductible, OPR_d , minus his/her out-of-pocket expenditures
43 $OOPE_{i,d}$ due to this deductible. Obviously, $C_{i,d}$ can also be a financial loss instead of a financial
44 gain.
45
46
47
48
49
50
51
52
53

$$54 C_{i,d} = OPR_d - OOPE_{i,d} \quad (8)$$

61
62
63
64
65

1
2
3 The data set contains information on the actual rebates for different deductible plans, but lacks
4 some information on expenditures for the insured whose expenditures did not exceed the deductible
5 amount, as mentioned in Section 4.2. To correct for unfiled claims we used the following three-step
6 procedure:
7
8
9

- 10
11
12 A) estimate an expenditure model on the group of insured *without* a voluntary deductible;
13
14 B) predict the expenditures of the insured *with* a voluntary deductible by combining their
15 characteristics with the coefficients obtained in A;
16
17 C) calculate the expected out-of-pocket expenditures using the results of B.
18
19
20
21
22

23 **5.2 Expected expenditures**

24 Expenditures of the insured without a voluntary deductible were assumed to be recorded in full.
25 This seems to be reasonable since only 18 percent of these insured had expenditures below the
26 mandatory deductible of CHF 230 and only 12 percent had no expenditures recorded at all. To
27 estimate the total expenditures $E(Y)_i$ we used the two-part model defined in equation (9).
28
29
30
31
32
33
34
35
36

$$37 E(Y)_i = p(Y_i > 0) * E(Y_i | Y_i > 0) \quad (9)$$

38
39
40
41 We estimated $p(Y_i > 0)$ by a logistic regression. For the estimation of the second part of
42 equation (9), we considered two options. The first, described by Duan et al. (1983), is applying OLS
43 to the logarithm of positive medical expenditures. An important disadvantage of this option with
44 regard to our analysis is that the predictions need to be retransformed to monetary units. The second
45 option is GLM with a log-link and a choice of distributions. We chose to use this option since the
46 predictions do not need to be retransformed and a distribution can be chosen that fits the data in a
47 proper way (Manning and Mullahy, 2001). The distribution chosen in our analysis reflects how the
48 variance is related to the mean. As will be described below, $E(Y)_i$ and its variance were finally used
49
50
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3 to estimate the out-of-pocket expenditures that concentrate in the left-tail of the distribution. Testing a
4 normal, log-normal, Poisson and Gamma distribution revealed that Gamma is the best in estimating
5 the out-of-pocket expenditures in our data. The fit will be illustrated later on. For the estimation of
6 both the first and the second part of equation (9) the following information was used to create the
7 explanatory variables: age, gender, region and gross expenditures in three previous years. Dummy
8 variables were created to represent 14 age/gender groups, and 9 different regions, and continuous
9 variables were created for the $\log(\text{gross expenditures} + 1)$ in years $t - 1$, $t - 2$ and $t - 3$ separately
10 for the 10 categories of medical care mentioned in Section 4.2.
11
12

13
14
15 As a next step, the coefficients obtained were used to predict the expenditures of the insured *with*
16 a voluntary deductible. For these insured the predicted expenditures were - a fraction $F(d)_0$ - higher
17 than the gross expenditures recorded in the data. Theoretically, this discrepancy can be the effect of
18 moral hazard, unfiled claims, and unobserved differences in health status. However, unobserved
19 differences in health status are expected to be insignificant, since differences in health and risk are
20 sufficiently captured by including prior expenditures of three preceding years in our model,
21 differentiated as well into ten types of expenditures. In the remainder of the analysis unobserved
22 differences in health status are assumed to be absent. Accordingly, the expected expenditures can be
23 seen as the expenditures that these insured would have had in a situation without a voluntary
24 deductible.
25
26

27
28
29 During the years in our data, the deductible levels did not change. So, given $F(d)_0$, the gross
30 expenditures in years $t - 1$, $t - 2$ and $t - 3$ were probably affected by moral hazard and unfiled
31 claims as well. This could have biased the prediction of expected expenditures in year t , since prior
32 expenditures were included in our model and most of the insured with voluntary deductible d in year
33 t had the same level of deductible in previous years. We corrected for this by multiplying the gross
34 expenditures in prior years by $1 + F(d)_0$. This further increased the relative difference in predicted
35 and gross expenditures in year t , because, obviously, expenditures in $t - 1$, $t - 2$ and $t - 3$ have a
36
37
38
39
40
41

1
2
3 positive impact on (predicted) expenditures in year t . As a result, the predicted expenditures for
4 insured with deductible d were on average - a fraction $F(d)_1$ - higher than the gross expenditures.
5
6 Accordingly, we multiplied the (original) gross expenditures in prior years (as recorded in the data)
7
8 by $1 + F(d)_1$, and so on. This iterative process converged after 8 steps, i.e.: $F(d)_s$ did not change
9
10 anymore (for $s \geq 8$).
11
12
13
14
15
16

17 **5.3 Expected out-of-pocket expenditures**

18
19 As a next step we wanted to predict the out-of-pocket expenditures due to the voluntary
20 deductible. Since all the insured in the data had a mandatory deductible of CHF 230, the total
21 deductible x equaled voluntary deductible $d + \text{CHF } 230$. The out-of-pocket expenditures of an
22 individual i due to his/her total deductible x were estimated according to equation (10).
23
24
25
26
27
28
29
30

$$31 \quad E(OOPE)_{i,x} = E(Y)_i * \Gamma(c_i, k + 1) + x * (1 - \Gamma(c_i, k)) \quad (10)$$

32
33
34
35
36 with

$$37 \quad c_i = x * \lambda_i \quad \text{and} \quad \lambda_i = k / E(Y)_i \quad (11)$$

38
39
40
41
42
43
44
45 and with $\Gamma(\cdot)$ the cumulative density function of the gamma distribution with parameters c and k
46
47 (Van Vliet 1995). Equation (10) can be seen as the weighted sum of the expected out-of-pocket
48 expenditures if medical expenditures are below x ($= E(Y)_i * \Gamma(c_i, k + 1) / \Gamma(c_i, k)$) and the out-of-
49 pocket expenditures if medical expenditures exceed x ($= x$). Respectively, the weighting factors are
50
51
52
53
54
55 $\Gamma(c_i, k)$ and $1 - \Gamma(c_i, k)$, i.e. the probability that $Y < x$ and the probability that $Y > x$ (Van Vliet
56
57
58 1995, 2004).
59
60
61
62
63
64
65

1
2
3
4 The final step in estimating the out-of-pocket expenditures $E(OOPE)_{i,d}$ due to a voluntary
5
6 deductible d was to subtract the expected out-of-pocket expenditures due to the *mandatory*
7
8 deductible of CHF 230 from the expected out-of-pocket expenditures due to the *total* deductible x .
9
10 We estimated the out-of-pocket expenditures due to the mandatory deductible the same way as the
11
12 total out-of-pocket expenditures, with x in (10) and (11) being replaced with 230. Table 2 shows the
13
14 average results per deductible.
15
16

17
18 The first row of table 2 shows what the expenditures of the five subgroups would have been in a
19
20 situation without a voluntary deductible. The difference with the first row of table 1 captures both
21
22 moral hazard and unfiled claims.
23
24
25

26
27 [Table 2]
28
29
30
31
32

33 **5.4 The necessary expenditure reduction due to less moral hazard**

34
35 As a final step we wanted to examine whether the premium rebates actually offered in 2003, could
36
37 have been offered in the presence of perfect risk equalization. With perfect risk equalization, the
38
39 premium rebate for a deductible can be based only on out-of-pocket expenditures and a reduction in
40
41 moral hazard, as argued in Section 3.1. In such a situation the actual rebates found in our data could
42
43 have been offered *only if* the expenditure reduction due to less moral hazard equals or exceeds the
44
45 actual financial gain found, as follows from equation (7) and (8). Accordingly, we calculated the
46
47 (relative) necessary expenditure reduction m according to equation (12).
48
49
50
51
52

$$53 \quad m = \bar{C}_d / \overline{E(Y)}_d \quad (12)$$

9

10 **6. Results**

11 **6.1 General statistics**

12
13
14
15
16 To quantify the actual financial gain for the insured with a deductible, we first estimated the total
17 expenditures and the out-of-pocket expenditures, as described in Section 5. Table 3 indicates the
18 validity of the procedure used to estimate the out-of-pocket expenditures. For the insured *without* a
19 voluntary deductible, it shows the *actual* values of expenditures between CHF 230 (mandatory
20 deductible level) and CHF 400, 600, 1200 and 1500 (total deductible levels) and the *predicted*
21 expenditures in these intervals. Notice that for these insured the *gross* expenditures on top of the
22 mandatory deductible of CHF 230 in year t are not affected by unfiled claims or reductions in moral
23 hazard. The *predicted* expenditures of these insured might be slightly affected by the corrections
24 described in Section 5.2. However, the effect is negligible since these corrections were only applied
25 to the gross expenditures of those with a voluntary deductible in one of the previous years; less than 3
26 percent of the insured *without* a deductible in year t had a voluntary deductible in $t - 1$, $t - 2$ and/or
27 $t - 3$. From table 3 it can be concluded that the predicted expenditures closely agree with the actual
28 expenditures in these intervals. The distribution test mentioned in Section 5.2 revealed that for the
29 normal, log-normal and Poisson distribution the correspondence between the actual and predicted
30 expenditures in these intervals was substantially poorer.

6.2 Potential gain for insured without a voluntary deductible

It could easily be calculated how large the average financial gain of those *without* a voluntary deductible would have been if they had collectively chosen a voluntary deductible. This quantity, which we define as the *potential* gain, is shown in table 4. It is calculated as the average premium rebate that these insured would have received for voluntary deductible d minus their average expected out-of-pocket expenditures due to d . This calculation ignores a possible reduction in moral hazard. If this would be taken into account as well then the potential gain would be even higher since a larger reduction in moral hazard might result in lower out-of-pocket expenditures.

From table 4 it can be concluded that on average a voluntary deductible would have been beneficial for these insured. Table 4 also shows the proportion of insured that would have had a (positive) financial gain. Of course, part of these insured knew for sure that their out-of-pocket expenditures would exceed the deductible amount due to a chronic illness, for instance. They were not likely to choose a deductible as long as the premium rebate did not (far) exceed the deductible amount. Nonetheless, table 4 reveals that this was definitely not the case for all the insured who did not choose a deductible. For 23 percent of these insured a voluntary deductible of CHF 170 would have been beneficial. This figure is 27 percent a voluntary deductible of CHF 370, 38 percent for a voluntary deductible of CHF 970 and 43 percent for a voluntary deductible of CHF 1,270. Apparently, these (ex-post) potential gains were not large enough to induce these insured to take a deductible.

[Table 4]

6.3 Actual financial gain in practice

After predicting the total expenditures for insured with voluntary deductible d we estimated their out-of-pocket expenditures according to equation (10) and (11). The average actual financial gain

1
2
3 could be calculated by subtracting the estimated out-of-pocket expenditures from the premium rebate
4
5 for voluntary deductible d . Table 5 shows the average actual gain per deductible in 2003.
6
7

8 We may not directly conclude that the actual financial gain exactly equals the *minimum*
9
10 compensation considered in Section 2. The reason is that some of the insured with deductible d
11
12 would possibly also have chosen d in return for a lower rebate. However, we expect that the
13
14 *minimum* compensation will not be far from the actual financial gain since the previous section
15
16 revealed that a substantial number of insured did not choose a deductible while it would have yielded
17
18 them a considerable financial advantage.
19
20
21

22 In general terms, these results indicate that the insurer had to offer a substantial premium rebate
23
24 (relative to the out-of-pocket expenditures) to induce almost 50 percent of the insured to take a
25
26 deductible. As described in Section 3, this is no problem in a health insurance market without *perfect*
27
28 risk equalization like the Swiss basic health insurance. Premium rebates in these insurance markets
29
30 can be very high because of the effect of self selection, despite the legal restrictions on premium
31
32 rebates.
33
34
35
36

37 **6.4 Necessary reduction in moral hazard**

38
39 If we assume risk equalization to adjust perfectly for differences in health status between the
40
41 insured with and the insured without a voluntary deductible, the premium rebate can be based only on
42
43 cost sharing plus the reduction in moral hazard, as argued in Section 3.1. The bottom row of table 5
44
45 shows how large the expenditure reduction due to less moral hazard had to be to offer the actual
46
47 premium rebates (found in the data) in the presence of perfect risk equalization. The reduction is
48
49 presented as a percentage of the average expected expenditures of the insured with d .
50
51
52
53
54
55

56 [Table 5]
57
58
59
60
61
62
63
64
65

1
2
3
4 To offer the actual rebate found for a voluntary deductible of CHF 170, the expenditure reduction
5 had to be 1.3 percent relative to the expected expenditures of these insured, *ceteris paribus*. For the
6 groups of insured having a voluntary deductible of CHF 370, 970 or 1,270 the reductions had to be
7
8 4.5, 20 and 48.8 percent, respectively.
9

10
11
12 To examine whether these reductions are likely to occur, these results can be compared with the
13 results discussed in Section 3.1. In the RAND-experiment an expenditure reduction of 31 percent was
14 found for a 95%-coinsurance plan with a maximum on out-of-pocket expenditures of \$1,000. This
15 plan can be seen as a high-deductible plan with the deductible amount being 134 percent (= \$1,000 / \$
16 749) of the average expenditures that insured were expected to have in case of full-coverage
17 (Manning et al., 1987). Van Vliet (2004) found that in the Dutch private health insurance of 1996 a
18 deductible of Dfl. 1,750 led to an expenditure reduction of 14 percent. This deductible amount was
19 about 69 percent (= Dfl. 1,750 / Dfl. 2,548) of the average expenditures that insured were expected to
20 have in case of full-coverage.
21
22

23
24 From table 2 it can be calculated that in our data a voluntary deductible of CHF 170 is about 5
25 percent (= CHF 170 / CHF 3,351) of the average expenditures that the insured with this deductible
26 were expected to have in a situation *without* a voluntary deductible. For voluntary deductibles of CHF
27 370, 970 and 1,270 these figures are 13 percent (= CHF 370 / CHF 2,929), 45 percent (= CHF 970 /
28 CHF 2,136) and 92 percent (= CHF 1,270 / CHF 1,373), respectively. Comparing the necessary
29 reduction with the results of Manning et al. (1987) and Van Vliet (1994), we conclude that the actual
30 rebate offered for a deductible of CHF 1,270 could definitely not have been offered in the presence of
31 “perfect” risk equalization. We should be careful with a conclusion regarding the deductible of CHF
32 970 because of the low number of insured having that deductible in our data. Regarding the
33 deductibles of CHF 170 and CHF 370 we conclude that the premium rebates actually offered could
34 probably also have been offered in the presence of perfect risk equalization.

1
2
3 With respect to the lower deductibles, i.e. CHF 170 and CHF 370, one should notice that these
4 results do not imply that a reduction of 1 percent will *always* be large enough to offer an attractive
5 premium rebate. If the voluntary deductible of CHF 170 would have been the highest deductible
6 available then the insured with voluntary deductibles of CHF 370, 970 and 1,270 in our dataset would
7 presumably have taken the voluntary deductible of CHF 170. Since these insured are on average
8 healthier, the average medical expenditures and average out-of-pocket expenditures in the group of
9 insured with a voluntary deductible of CHF 170 would have been lower. Consequently, the necessary
10 expenditure reduction would have been larger, according to equation (12).

18
19
20
21
22

23 **7. Conclusion and policy implications**

24
25
26 Theoretically, a risk averse consumer takes a voluntary deductible *only if* the premium rebate
27 exceeds his/her expected out-of-pocket expenditures, i.e. if he/she expects to obtain a financial gain.
28 In our 2003-data from Switzerland we found that the actual rebates for voluntary deductible d (far)
29 exceeded the average out-of-pocket expenditures for insured with d . Moreover, our results reveal
30 that a substantial number of insured did not choose a deductible although it would have yielded them
31 a considerable financial advantage. This indicates that consumers demand a large financial
32 compensation in order to be induced to take a (high) deductible.
33
34
35
36
37
38
39
40
41

42 In the *absence* of (perfect) risk equalization insurers can offer high premium rebates due to the
43 effect of self selection. We conclude that, for high deductibles, such premium rebates cannot be
44 offered in the *presence* of “perfect” risk equalization. In such a situation numbers of insured opting
45 for a high deductible will be lower and the total reduction in moral hazard will be smaller than in the
46 *absence* of (perfect) risk equalization.
47
48
49
50
51
52
53

54
55
56 The Swiss and the Dutch 2006-equalization schemes are “imperfect”, implying that part of the
57 expenditure differences between the insured with and without voluntary deductible d can be
58
59
60
61
62
63
64
65

1
2
3 reflected in the premium rebate for d . As a result, the level of cross-subsidization between the
4
5 healthy and the unhealthy insured is lower than in a situation with perfect risk equalization. One way
6
7 to increase cross-subsidization would be to include the level of deductible as a risk factor in the
8
9 equalization model. Risk equalization would then “perfectly” adjust for differences in health status
10
11 between those who choose a deductible and those who do not. As shown in this paper, this would also
12
13 lead to less insured choosing a deductible and a smaller reduction in moral hazard. Since the main
14
15 goal of user charges is to reduce moral hazard, some effect of self selection on the premium rebate
16
17 can be justified to increase the viability of voluntary deductibles.

Figures

Figure 1 The demand for insurance (p=0.5)

Figure 2 The maximum loading fee (p=0.5)

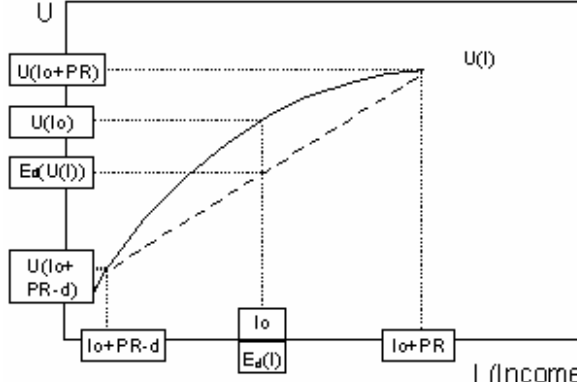

Figure 3 The demand for deductibles (p=0.5)

Figure 4 The minimum compensation ($p=0.5$)

Tables

Table 1 Mean (std dev) per deductible level in 2003 (currency = CHF; CHF 1 = € 0.63)

	x=230 d=0	x=400 d=170	x=600 d=370	x=1,200 d=970	x=1,500 d=1,270
Gross expenditures	3,874 (7,422)	2,967 (6,298)	2,457 (5,888)	1,743 (5,927)	884 (2,732)
Expenditures > CHF 1,500	2,826 (7,224)	2,020 (6,087)	1,670 (5,644)	1,184 (5,701)	489 (2,464)
Proportion of insured with expenditures > 1,500	0.54 (0.50)	0.46 (.50)	0.37 (0.48)	0.25 (0.43)	0.15 (0.36)
Age	59 (16)	57 (14)	54 (14)	53 (14)	48 (11)
N (total = 134,758)	71,864	30,457	11,305	3,303	17,829

Table 2 Mean (std dev) of expected (out-of-pocket) expenditures per deductible level in 2003 (currency = CHF; CHF 1 = € 0.63)

	x=230 d=0	x=400 d=170	x=600 d=370	x=1,200 d=970	x=1,500 d=1,270
Expected expenditures E(Y)	3,876 (4,102)	3,351 (3,617)	2,929 (3,961)	2,136 (3,440)	1,373 (1,735)
Expected out-of-pocket expenditures due to the <i>total</i> deductible x	195 (47)	314 (89)	408 (154)	596 (314)	566 (343)
Expected out-of-pocket expenditures due to the <i>mandatory</i> deductible	195 (47)	188 (50)	172 (58)	147 (62)	134 (61)
Expected out-of-pocket expenditures due to the <i>voluntary</i> deductible d	0 (0)	126 (39)	236 (96)	449 (253)	432 (285)

Table 3 Mean (std dev) of actual and predicted expenditures between CHF 230 and CHF x for the insured *without* a voluntary deductible in 2003 (N=71,864; currency = CHF; CHF 1 = € 0.63)

	Actual expenditures	Predicted expenditures
Between CHF 230 and 400	135 (67)	135 (36)
Between CHF 230 and 600	286 (148)	284 (79)
Between CHF 230 and 1,200	682 (403)	678 (215)
Between CHF 230 and 1,500	852 (531)	850 (284)

Table 4 Potential gain for insured *without* a voluntary deductible in 2003 (N=71,864; currency = CHF; CHF 1 = € 0.63)

	d = 170	d = 370	d = 970	d = 1,270
Premium rebate	170	367	877	1,116
Predicted expenditures between CHF 230 and CHF 230+d	135	284	678	850
Average potential gain	35	83	199	266
Proportion of insured with potential gain > 0	0.23	0.27	0.38	0.43

Table 5 Average financial gain due to voluntary deductible d for all insured with d in 2003 (currency = CHF; CHF 1 = € 0.63)

	d = 170	d = 370	d = 970	d = 1,270
Premium rebate	170	367	877	1,116
$E(OOPE)_d$	126	236	449	432
Average gain	44	131	427	684
Average gain as % of $E(OOPE)_d$	35%	56%	95%	158%
Average gain as % of $E(Y)$	1.3%	4.5%	20.0%	48.8%
